The codedescribe and codelisting Packages Version 1.18

Alceu Frigeri*

November 2025

Abstract

This package is designed to be as class independent as possible, depending only on expl3, scontents, listing, xpeekahead and pifont. Unlike other packages of the kind, a minimal set of macros/commands/environments is defined: most/all defined commands have an "object type" as a keyval parameter, allowing for an easy expansion mechanism (instead of the usual "one set of macros/environments" for each object type).

No assumption is made about page layout (besides "having a marginpar"), or underlying macros, so it should be possible to use these with any/most document classes.

1 Introduction

This package aims to document both Document level (i.e. final user) commands, as well Package/Class level commands. It's fully implemented using expl3 syntax and structures, in special 13coffins, 13seq and 13keys. Besides those scontents and listing packages (see [1] and [2]) are used to typeset code snippets. The package pifont is needed just to typeset those (open)stars, in case one wants to mark a command as (restricted) expandable.

^{*}https://github.com/alceu-frigeri/codedescribe

No other package/class is needed, and it should be possible to use these packages with most classes¹, which allows to demonstrate document commands with any desired layout.

codelisting defines a few macros to display and demonstrate LATEX code (using listings and scontents), codedescribe defines a series of macros to display/enumerate macros and environments (somewhat resembling the doc3 style), and codelstlang defines a series of listings TeX dialects.

1.1 Single versus Multi-column Classes

This package "can" be used with multi-column classes, given that the \linewidth and \columnsep are defined appropriately. \linewidth shall defaults to text/column real width, whilst \columnsep, if needed (2 or more columns) shall be greater than \marginparwidth plus \marginparsep.

1.2Current Version

All packages (codedescribe, codelisting, codelstlang and codedescsets) share the same version, currently: 1.18. Those packages are fairly stable, and given the obj-type mechanism (see 3.2) they can be easily extended without changing their interface.

2 codelisting Package

It requires two packages: listings and scontents, defines an environment: codestore, a few commands for listing/demo code: \tscode, \tsmergedcode, \tscdemo, \tsresult and \tsexec and 2 auxiliary commands: \setcodekeys and \setnewcodekey.

2.1 **Package Options**

The following options are also codedescribe options, see 3.1.

load xtra dialects

(defaults to false) If set, it will load the auxiliary package codelstlang (see 4), which just defines a series of listings TeX dialects.

TeX dialects This will set which listings TeX dialects will be used when defining the listing style codestyle. It defaults to doctools, which is derived from the [LaTeX]TeX dialect (this contains the same set of commands used by the package doctools). One can use any valid (TeX derived) listings dialect, including user defined ones, see [2] for details.

> Besides those, one can use (if the load xtra dialects is set): 13kernelsign, 13expsign, 13amssign, 13pgfsign, 13bibtexsign, 13kernel, 13exp, 13ams, 13pgf, 13bibtex, kernel, xpacks, ams, pgf, pgfplots, bibtex, babel and hyperref. See 4 for details on those dialects.

> > Note: TeX dialects is a comma separated list of the dialect's name, without the base language (internally it will be converted to [dialect] TeX).

For example:

```
%% could be \usepackage[...]{codelisting}
\usepackage[load xtra dialects.
 TeX dialects={doctools,13kernel,13ams}]{codedescribe}
   %%
   %% assuming the user has defined a dialect, named: [my-own-set]TeX
   %%
\usepackage[TeX dialects={doctools,my-own-set}]{codedescribe}
```

¹If, by chance, a class with compatibility issues is found, just open an issue at https://github.com/ alceu-frigeri/codedescribe/issues to see what can be done

2.2 In Memory Code Storage

Thanks to scontents (expl3 based) it's possible to store LATEX code snippets in a expl3 sequence variable.

codestore

```
\label{local_codestore} $$ \left[ \left\langle \text{stcontents-keys} \right\rangle \right] $$ \end{codestore} $$
```

This environment is an alias to scontents environment (from scontents package, see [1]), all scontents keys are valid, with two additional ones: st and store-at which are aliases to the store-env key. If an "isolated" (st-name) is given (unknown key), it is assumed that the environment body shall be stored in it (for use with \tscode, \tsmergedcode, \tsdemo, \tsresult and \tsexec).

Note: From scontents, $\langle \text{st-name} \rangle$ is $\langle \text{index} \rangle \text{ed}$ (The code is stored in a sequence variable). It is possible to store as many code snippets as needed under the same name. The first one will be $\langle \text{index} \rangle \rightarrow 1$, the second 2, and so on.

Warning: If explicitly using one of the store-env, st or store-at keys, the storage name can be anything. BUT, due to changes (August 2025) in the latex kernel keys processing, if an implicitly key is used, then colons (:), besides a comma and equal signs, aren't allowed.

LATEX Code:

```
%The code will be stored as 'store:A'
\begin{codestore}[store-env = store:A]
...
\end{codestore}

%Same
\begin{codestore}[st = store:A]
...
\end{codestore}

%The code will be stored as 'storeA'
\begin{codestore}[storeA]
...
\end{codestore}

%This might raises an error.
%It will be stored as 'store' (not as 'store:A')
\begin{codestore}[store:A]
...
\end{codestore}
```

2.3 Code Display/Demo

\tscode*
\tsdemo*
\tsresult*

```
\label{tscode*} $$ \code-keys \] {\langle st-name \rangle} [\langle index \rangle] $$ \tsdemo* [\langle code-keys \rangle] {\langle st-name \rangle} [\langle index \rangle] $$ \tsresult* [\langle code-keys \rangle] {\langle st-name \rangle} [\langle index \rangle] $$
```

updated: 2024/01/06 updated: 2025/04/29 \tscode* just typesets (st-name) (created with codestore) verbatim with syntax highlight (from listings package [2]). The non-star version centers it and use just half of the base line. The star version uses the full text width.

\tsdemo* first typesets \(\st-name \), as above, then executes it. The non-start version place them side-by-side, whilst the star version places one following the other.

(new 2024/01/06) \tsresult* only executes it. The non-start version centers it and use just half of the base line, whilst the star version uses the full text width.

Note: (from stcontents package) $\langle index \rangle$ can be from 1 up to the number of stored codes under the same $\langle st-name \rangle$. Defaults to 1.

Note: All are executed in a local group which is discarded at the end. This is to avoid unwanted side effects, but might disrupt code execution that, for instance, depends on local variables being set. That for, see \tsexec below.

For Example:

LATEX Code:

```
\begin{codestore} [stmeta]
    Some \LaTeX{} coding, for example: \ldots.
\end{codestore}
This will just typesets \tsobj[key]{stmeta}:
\tscode*[codeprefix={Sample Code:}] {stmeta}
and this will demonstrate it, side by side with source code:
\tsdemo[numbers=left,ruleht=0.5,
    codeprefix={inner sample code},
    resultprefix={inner sample result}] {stmeta}
```

LATEX Result:

This will just typesets stmeta:

Sample Code:

```
Some \LaTeX{} coding, for example: \ldots.
```

and this will demonstrate it, side by side with source code:

inner sample code

inner sample result

Some \LaTeX{} coding, for example: \ldots.

Some LATEX coding, for example:

\tsmergedcode*

 $\verb|\tsmergedcode*| [\langle code-keys \rangle] {\langle st-name-index list \rangle}|$

new: 2025/04/29

This will typeset (as \tscode) the merged contents from $\langle st-name-index list \rangle$. The list syntax comes from scontents (command \mergesc), where it is possible to refer to a single index $\{\langle st-name A \rangle\}$ [$\langle index \rangle$], a index range $\{\langle st-name B \rangle\}$ [$\langle index A-index B \rangle$], or all indexes from a $\langle st-name \rangle$, $\{\langle st-name C \rangle\}$ [$\langle 1-end \rangle$]. The special index $\langle 1-end \rangle$ refers to all indexes stored under a given $\langle st-name \rangle$.

Note: The brackets aren't optional. For instance \tsmergedcode* [$\langle code-keys \rangle$] { $\{\langle st-name\ A \rangle\}$ [$\langle index \rangle$], $\{\langle st-name\ B \rangle\}$ [$\langle index A-index B \rangle$], $\{\langle st-name\ C \rangle\}$ [$\langle 1-end \rangle$]}

\tsexec

\tsexec $\{\langle st-name \rangle\}$ [$\langle index \rangle$]

new: 2025/04/29

Unlike the previous commands which are all executed in a local group (discarded at the end) this will execute the code stored at st-name [(index)] in the current LATEX group.

2.3.1 Code Keys

\setcodekeys

\setcodekeys $\{\langle code-keys \rangle\}$

One has the option to set $\langle code-keys \rangle$ per \tscode, \tsmergedcode, \tsdemo and \tsresult call (see 2.3), or globally, better said, in the called context group.

N.B.: All \tscode and \tsdemo commands create a local group in which the \(\)code-keys\(\) are defined, and discarded once said local group is closed. \(\)setcodekeys defines those keys in the \(\)current context/group.

\setnewcodekey

 $\strut {\code-keys} {\code-keys}$

ew: 2025/05/01

This will define a new key $\langle new-key \rangle$, which can be used with \tscode, \tsmergedcode, \tsdemo and \tsresult. $\langle code-keys \rangle$ can be any of the following ones, including other $\langle new-key \rangle$ s. Be careful not to create a definition loop.

lststyle

lststyle

new: 2025/11/22

This sets the base style to be used. It defaults to <code>codestyle</code>, and the user can use this (<code>codestyle</code>) as the base style for his own one (and avoid having to define every single aspect of it). For example:

```
% see the listings manual for a complete list of keywords
\lstdefinestyle{my-own}{
 style=codestyle,
  texcsstyle
                           {\bfseries\color{red}}
\tscode*[lststyle=my-own]{demo-X}
```

settexcs

settexcs, settexcs2, settexcs3 and settexcs4

texcs

texcs, texcs2, texcs3 and texcs4

texcsstyle

texcsstyle, texcs2style, texcs3style and texcs4style

updated: 2025/05/01 These define sets of IATEX commands (csnames, sans the preceding slash bar), the set variants initialize/redefine those sets (an empty list, clears the set), while the others extend those sets. The style ones redefines the command display style (an empty \(\nabla \text{nlue} \) resets the style to it's default).

setkeywd keywd keywdstyle setkeywd, setkeywd2, setkeywd3 and setkeywd4

keywd, keywd2, keywd3 and keywd4

keywdstyle, keywd2style, keywd3style and keywd4style

2025/05/01 updated:

Same for other *keywords* sets.

setemph emph emphstyle setemph, setemph2, setemph3 and setemph4

emph, emph2, emph3 and emph4

emphstyle, emph2style, emph3style and emph4style

2025/05/01 updated:

for some extra emphasis sets.

letter other

letter and other

These allow to redefine what a letter or other are (they correspond to the alsoletter and alsoother keys from listings). The default value for the letter includes (sans the comma) _ , whilst other default value is an empty list.

> Note: You might want to consider setting letter to just letter={0,_} so you don't have to list all variants, but just the base name of an expl3 function.

numbers

numbers and numberstyle

number style

numbers possible values are none (default) and left (to add tinny numbers to the left of the listing). With numberstyle one can redefine the numbering style.

stringstyle

stringstyle and commentstyle

codestyle

to redefine strings and comments formatting style.

bckgndcolor

bckgndcolor

to change the listing background's color.

codeprefix

codeprefix and resultprefix

resultprefix

those set the codeprefix (default: LATEX Code:) and resultprefix (default: LATEX Result:)

parindent

parindent

Sets the indentation to be used when 'demonstrating' LATEXcode (\tsdemo). Defaults to whatever value \parindent was when the package was first loaded.

ruleht

When typesetting the 'code demo' (\tsdemo) a set of rules are drawn. The Default, 1, equals to \arrayrulewidth (usually 0.4pt).

basicstyle

2023/11/18

Sets the base font style used when typesetting the 'code demo', default being \footnotesize \ttfamily

3 codedescribe Package

This package aims at minimizing the number of commands, being the object kind (if a macro, or environment, or variable, or key ...) a parameter, allowing for a simple extension mechanism: other object types can be easily introduced without having to change, or add commands.

3.1 Package Options

nolisting it will suppress the *codelisting* package load. In case it isn't needed or another listing package will be used.

label set (new: 2025/11/22) This allows to pre-select a label set, see 3.3. Currently, the possible values are english, german and french, the ones present in the auxiliary package codedescsets.

base skip Changes the base skip, all skips (used by the environments at 3.4) are scaled up from this. It defaults to the font size at load time.

strict Package Warnings will be reported as Package Errors.

silence (new: 2025/11/22, defaults to 18.89999pt) This will suppress some annoying bad boxes warnings. Given the way environments at 3.4 are defined, with expl coffins, TeX thinks they are too wide, when they are not.

color scheme Possible values: black, default, brighter and darker. This will adjust the initial color configuration for the many format groups/objects (see 3.2.1). black will defaults all \tsobj colors to black. default, brighter and darker are roughly the same color scheme. The default scheme is the one used in this document. With brighter the colors are brighter than the default, and with darker the colors will be darker, but not black.

Note: color scheme doesn't affect codelisting / listings colors.

load xtra dialects This will be passed over to codelisting package (if loaded). See 2.1.

TeX dialects This will be passed over to codelisting package (if loaded). See 2.1.

3.2 Object Type keys

(obj-types) defines the applied format, which is defined in terms of (format-groups) wich defines a formatting function, font shape, bracketing, etc. to be applied.

3.2.1 Format Keys

Those are the primitive $\langle format-keys \rangle$ used when (re)defining $\langle format-groups \rangle$ and $\langle obj-types \rangle$ (see 3.2.4):

meta to typeset between angles,

xmeta to typeset *verbatim* between angles,

verb to typeset *verbatim*,

xverb to typeset *verbatim*, suppressing all spaces,

code to typeset *verbatim*, suppressing all spaces and replacing a TF by TF,

nofmt in case of a redefinition, to remove the 'base' formatting,

slshape to use a slanted font shape, itshape to use an italic font shape,

noshape in case of a redefinition, to remove the 'base' shape,

lbracket defines the left bracket (when using \tsargs). Note: this key must have an

associated value,

rbracket defines the right bracket (when using \tausass). Note: this key must have an

associated value,

defines the text color. **Note:** this key must have an associated value (a color,

as understood by xcolor package).

3.2.2 Format Groups

Using \defgroupfmt (see 3.2.4) one can (re-)define custom \(format-groups \). The following ones are predefined:

metawhich sets meta and colorverbwhich sets coloroargwhich sets meta and colorcodewhich sets code and colorsyntaxwhich sets color

keyval which sets slshape and color

option which sets color defaultval which sets color

env which sets slshape and color pkg which sets slshape and color

Note: color was used in the list above just as a 'reminder' that a color is defined/associated with the given group, it can be changed with \defgroupfmt.

3.2.3 Object Types

Object types are the <code>keys</code> used with <code>\tsobj</code> (and friends, see 3.5) defining the specific formatting to be used. With <code>\defobjectfmt</code> (see 3.2.4) one can (re-)define custom <code>obj-types</code>. The predefined ones are:

arg, meta based on (group) meta verb, xverb based on (group) verb plus verb or xverb marg based on (group) meta plus brackets oarg, parg, xarg based on (group) oarg plus brackets code, macro, function based on (group) code based on (group) syntax syntax keyval, key, keys, values based on (group) keyval option based on (group) option defaultval based on (group) defaultval based on (group) env env based on (group) pkg pkg, pack

3.2.4 Customization

To create user defined groups/objects or change the pre-defined ones:

\defgroupfmt

```
\displaystyle \operatorname{defgroupfmt} \{\langle \operatorname{format-group} \rangle\} \{\langle \operatorname{format-keys} \rangle\}
```

new: 2023/05/16

(format-group) is the name of the new group (or one being redefined, which can be one of the standard ones). (format-keys) is any combination of the keys from 3.2.1

For example, one can redefine the *code group* standard color with \defgroupfmt{code}{color=red} and all *obj-types* based on it will be typeset in red (in the standard case: *code*, *macro* and *function* objects).

\defobjectfmt

```
\label{lem:defobjectfmt} $$ \ensuremath{ \langle \text{obj-type} \rangle } {\langle \text{format-group} \rangle} {\langle \text{format-keys} \rangle} $$
```

new: 2023/05/16

 $\langle obj-type \rangle$ is the name of the new $\langle object \rangle$ being defined (or redefined), $\langle format-group \rangle$ is the base group to be used (see 3.2.2). $\langle format-keys \rangle$ (see 3.2.1) allow for further differentiation.

For instance, the many optional (*arg) are defined as follow:

```
\colorlet {c_codedesc_oarg_color} { gray!90!black }
\defgroupfmt {oarg} { meta , color=c_codedesc_oarg_color }
\defobjectfmt {oarg} {oarg} { lbracket={[] , rbracket={]] } }
\defobjectfmt {parg} {oarg} { lbracket={(] , rbracket={)] } }
\defobjectfmt {xarg} {oarg} { lbracket={<} , rbracket={>} }
```

3.3 Locale

The following commands allows to customize the many 'labels' in use, in particular the auxiliary package *codedescsets* holds a few locale sets, the user is invited to submit translations for a specific case/language via a PR (Push Request) at https://github.com/alceu-frigeri/codedescribe

\setcodelabels
\newlabelset
\selectlabelset

```
\label{labels} $$\operatorname{\langle labels-list\rangle}$ \newlabelset $$\{\langle lang\rangle\} $$\{\langle labels-list\rangle\}$ $$\> \cline{1.5}$
```

new: 2025/11/22

\setcodelabels allows to change the many 'labels' used (like 'updated' in the codedescribe environment). See below for a complete list of possible labels, it can be used at any time, allowing to change those labels mid text.

\newlabelset will create a label's set (named as $\langle lang \rangle$) for later use with \selectlabelset (akin of a language locale), while \selectlabelset will select (activate) the given set. They can also be used at any time.

The (labels-list) can be any combination of:

new It set's the 'new' label used in the codedescribe environment.

update It set's the 'update' label used in the codedescribe environment.

note It set's the 'note' label used in the codedescribe environment.

and It set's the 'and' label used by \tsobj (hint: last item separator).

or It set's the 'or' label used by \tsobj (hint: last item separator).

months It set's the month list used by \tsobj (hint: last item separator).

It set's the month list used by \tsobj (hint: last item separator).

Note: \newlabelset is used in the auxiliary package codedescsets to predefine some sets, which can then be used as a package option, see 3.1.

Note: The given $\langle labels-list \rangle$ doesn't need to be complete, though, only the given labels will be changed.

For example, this sets a new label set for German. In fact, since this is defined in the package codedescsets this label set can be used when loading this package, see 3.1.

```
\newlabelset {german}
 {
   new
            = neu
   update
            = aktualisiert
            = NB
   note
   remark
            = Hinweis
            = und
   and
            = oder
   or
    months
      {
        Januar, Februar, März, April,
        Mai, Juni, Juli, August,
        September, Oktober, November, Dezember
```

3.4 Environments

codedescribe

new: 2023/05/01 updated: 2023/05/01 updated: 2024/02/16 updated: 2025/09/25 NB: a note example

```
\label{localization} $$ \left[ \left\langle \text{obj-keys} \right\rangle \right] \left\{ \left\langle \text{csv-list} \right\rangle \right\} $$
```

. . .

\end{codedescribe}

This is the main environment to describe Commands, Variables, Environments, etc. (csv-list) items will be listed in the left margin. The optional (obj-keys) defaults to just code, it can be any object type as defined at 3.2.3 (and 3.2.4), besides the following keys:

new To add a new line. update To add an updated line. note To add a NB line.

rulecolor For instance \begin{codedescribe}[rulecolor=white] will suppress the rules.

EXP A star ★ will be added to all items, signaling the commands are fully expand-

able.

rEXP A hollow star \Leftrightarrow will be added to all items, signaling the commands are

restricted expandable.

Note: The keys new, update and note can be used multiple times. (2024/02/16)

Note: If using one of the keys new, update, note, rulecolor, EXP or rEXP the user must also provide an object type. code is the solely default IF nothing else is provided.

Note: With the strict package option an error will be raised if used inside another *codedescribe* environment. Otherwise a warning will be raised. (it's safe to do so, but it doesn't make much sense).

codesyntax

updated: 2025/09/25

\begin{codesyntax}

. . .

\end{codesyntax}

The codesyntax environment sets the fontsize and activates \obeylines, \obeyspaces, so one can list macros/cmds/keys use, one per line.

Note: codesyntax environment shall appear only once, inside of a codedescribe environment. Take note, as well, this is not a verbatim environment!

Note: With the strict package option an error will be raised if used outside a *codedescribe* environment, or more than once inside. Otherwise a warning will be raised.

For example, the code for codedescribe (previous entry) is:

LATEX Code:

describelist describelist*

\end{describelist}

This sets a description like 'list'. In the non-star version the \(\)items-name\(\) will be typeset on the marginpar. In the star version, \(\)item-description\(\) will be indented by \(\)item-indent\(\) \(\) (defaults to: 20mm\(\)). \(\)obj-type\(\) defines the object-type format used to typeset \(\)item-name\(\).

\describe

 $\label{lem-name} $$\describe {\langle item-name \rangle} {\langle item-description \rangle}$$

This is the describelist companion macro. In case of the describe*, (item-name) will be typeset in a box (item-ident) wide, so that (item-description) will be fully indented, otherwise (item-name) will be typed in the marginpar.

Note: An error will be raised (undefined control sequence) if called outside of a describelist or describelist* environment.

3.5 Typeset Commands

Note that, in the following commands, $\langle obj-type \rangle$ refers to any object type defined in 3.2.3 and 3.2.4.

\typesetobj \tsobj

```
\label{typesetobj} $$ \tsobj [\langle obj-type \rangle] {\langle csv-list \rangle} $$ \tsobj [\langle obj-type \rangle] {\langle csv-list \rangle} $$
```

updated: 2025/05/29

This is the main typesetting command, each term of $\langle csv-list \rangle$ will be separated by a comma and formatted as defined by $\langle obj-type \rangle$ (defaults to code). $\langle obj-type \rangle$ can be any object from 3.2.3 (or 3.2.4) and the following keys:

To change the item separator. Defaults to a comma, can be anything.

To change the separator between the last two items. Defaults to "and".

To set the separator between the last two items to "or".

To set the separator between the last two items to a comma.

bnf or

To produce a bnf style or list, like [abc|xdh|htf|hrf].

To produce a bnf style or list between angles, like (abc|xdh|htf|hrf).

To produce a bnf style or list between parentheses, like (abc|xdh|htf|hrf).

\typesetargs
\tsargs

```
\label{typesetargs} $$ \left[\langle \text{obj-type} \right] {\langle \text{csv-list} \rangle} \right] $$ \left[\langle \text{obj-type} \right] {\langle \text{csv-list} \rangle} $$
```

These will typeset $\langle csv-list \rangle$ as a list of parameters, like $[\langle arg1 \rangle] [\langle arg2 \rangle] [\langle arg3 \rangle]$, or $\{\langle arg1 \rangle\} \{\langle arg2 \rangle\} \{\langle arg3 \rangle\}$, etc. $\langle obj-type \rangle$ defines the formating AND kind of brackets used (see 3.2): [] for optional arguments (oarg), {} for mandatory arguments (marg), and so on.

\typesetmacro \tsmacro

```
\label{limits} $$ \operatorname{{\rm corgs-list}} {(\operatorname{macro-list})} [(\operatorname{oargs-list})] {(\operatorname{margs-list})} \to {(\operatorname{macro-list})} [(\operatorname{oargs-list})] ((\operatorname{margs-list})) }
```

These are just short-cuts for

\tsobj[code]{macro-list} \tsargs[oarg]{oargs-list} \tsargs[marg]{margs-list}.

\typesetmeta \tsmeta

```
\typesetmeta \{\langle name \rangle\} \tsmeta \{\langle name \rangle\}
```

These will just typeset (name) between left/right 'angles' (no further formatting).

\typesetverb \tsverb

```
\typesetverb [\langle obj-type \rangle] {\langle verbatim text \rangle }
\tsverb [\langle obj-type \rangle] {\langle verbatim text \rangle }
```

Typesets (verbatim text) as is (verbatim...). (obj-type) defines the used format. The difference with \tsobj [verb]{something} is that (verbatim text) can contain commas (which, otherwise, would be interpreted as a list separator by \tsobj.

Note: This is meant for short expressions, and not multi-line, complex code (one is better of, then, using 2.3). (verbatim text) must be balanced! otherwise, some low level TpX errors might pop out.

Note/Remark Commands 3.6

\tsmarginnote

\typesetmarginnote \typesetmarginnote $\{\langle note \rangle\}$ \tsmarginnote $\{\langle note \rangle\}$

Typesets a small note at the margin.

tsremark

\begin{tsremark} $[\langle NB \rangle]$ \end{tsremark}

The environment body will be typeset as a text note. (NB) (defaults to Note:) is the note begin (in boldface). For instance:

L⁴TEX Code:

LATEX Result:

Sample text. Sample test. \begin{tsremark}[N.B.] This is an example. \end{tsremark}

Sample text. Sample test. **N.B.** This is an example.

3.7 **Auxiliary Commands and Environment**

In case the Document Class being used redefines the \maketitle command and/or abstract environment, alternatives are provided (based on the article class).

\tstitle

 $\verb|\typesettitle | typesettitle {$\langle title-keys \rangle$}|$ \tstitle {\ditle-keys\}

This is based on the \maketitle from the article class. The \tangle title-keys\rangle are:

title The title.

author Author's name. It's possible to use the \footnote command in it.

Title's date. date

> Note: The \footnote (inside this) will use an uniquely assigned counter, starting at one, each time this is used (to avoid hyperref warnings).

tsabstract

\begin{tsabstract}

\end{tsabstract}

This is the abstract environment from the article class.

\typesetdate \tsdate

\typesetdate

\tsdate

2023/05/16

This provides the current date (in Month Year, format).

4 codelstlang Package

This is an auxiliary package (which can be used on its own). It assumes the package <code>listings</code> was already loaded, and just defines the following TEX dialects, all of them derived from (listings) <code>[LaTeX]TeX</code>:

- [13kernelsign] TeX Most/all exp1 keys found in the 13kernel[3] packages, including signatures.
 - [13expsign]TeX Most/all exp1 keys found in the 13kernel experimental packages, including signatures.
 - [13amssign] TeX Most/all exp1 keys found in the ams, siunitx and related packages, including signatures.
 - [13pgfsign] TeX Most/all exp1 keys found in the pgf and related packages, including signatures.
- [13bibtexsign] TeX Most/all expl keys found in the bibtex, biblatex and related packages, including signatures.

Note: The underscore '_' and colon ':' have to be defined as letters (letter = $\{$ _ , : $\}$, see 2.3.1). Take note that those dialects are quite large, due the many signatures variants.

- [13kernel] TeX Most/all expl keys found in the 13kernel packages, without signatures.
 - [13exp]TeX Most/all expl keys found in the 13kernel experimental packages, without signatures.
 - [13ams] TeX Most/all expl keys found in the ams, siunitx and related packages, without signatures.
 - [13pgf]TeX Most/all expl keys found in the pgf and related packages, without signatures.
- [13bibtex] TeX Most/all expl keys found in the bibtex, biblatex and related packages, without signatures.

Note: The underscore '_' has to be defined as letter (letter = $\{\ _\ \}$, but not the colon ':', see 2.3.1). Those are more compact versions of the previous ones.

- [kernel] TeX Most/all document level keys found in the kernel packages.
- [xpacks]TeX Most/all document level keys found in the x* packages, like xkeyval, xpatch, xcolor etc.
 - [ams] TeX Most/all document level keys found in the ams, siunitx and related packages.
 - [pgf]TeX Most/all document level keys found in the pgf and related packages.
- [pgfplots] TeX Most/all document level keys found in the pgfplots and related packages.
 - [bibtex] TeX Most/all document level keys found in the bibtex, biblatex and related packages.
 - [babel] TeX Most/all document level keys found in the babel and related packages.
- [hyperref] TeX Most/all document level keys found in the hyperref and related packages.

Note: Those are usual document level, LaTeX 2ε , commands. In particular none of them includes any '@' symbol.
